

A scenic view of a rocky coastline with turquoise water and a clear blue sky. The foreground shows dark, jagged rocks with some green vegetation and palm trees. The water transitions from a shallow turquoise near the shore to a deeper blue further out. The sky is a uniform, clear blue.

# Introduction to Physical Oceanography

Fall 2013

Professor Galen A. McKinley

# Introductions

- Who are you?
  - Background, interests, a fun fact
- Why are you interested in oceanography?
- Share a personal experience with the ocean.

# Why Oceanography?

- Oceans cover 71% of planet – a critical earth system component
- Climate – including variability and change on daily to geologic timescales
- Biosphere -- 50% of all species on Earth
- Critical resource for human civilization
- Natural phenomena -> human disaster

# Our Focus

- Oceans in the climate system
  - Basic state, circulation, waves, tides
  - Interaction with the atmosphere
- Dynamics of a fluid on a rotating planet
  - How does the circulation come about?
- Climate variability and change
  - Circulation
  - Biogeochemistry – Primary productivity and Carbon cycling

# Oceans in the climate system

A scenic view of a rocky coastline. In the foreground, there are dark, jagged rocks with some green vegetation and palm trees. The water is a vibrant turquoise color, transitioning to a deeper blue as it extends to the horizon. The sky is a clear, light blue. The text "The oceans carry heat from equator to pole" is overlaid in the center of the image.

The oceans carry heat from  
equator to pole

# Earth is unevenly heated by the Sun

(Modified from Hartmann, 1994.)

Motions of the Earth's fluid envelope carry much heat from tropics to pole.

M&P fig 8.1

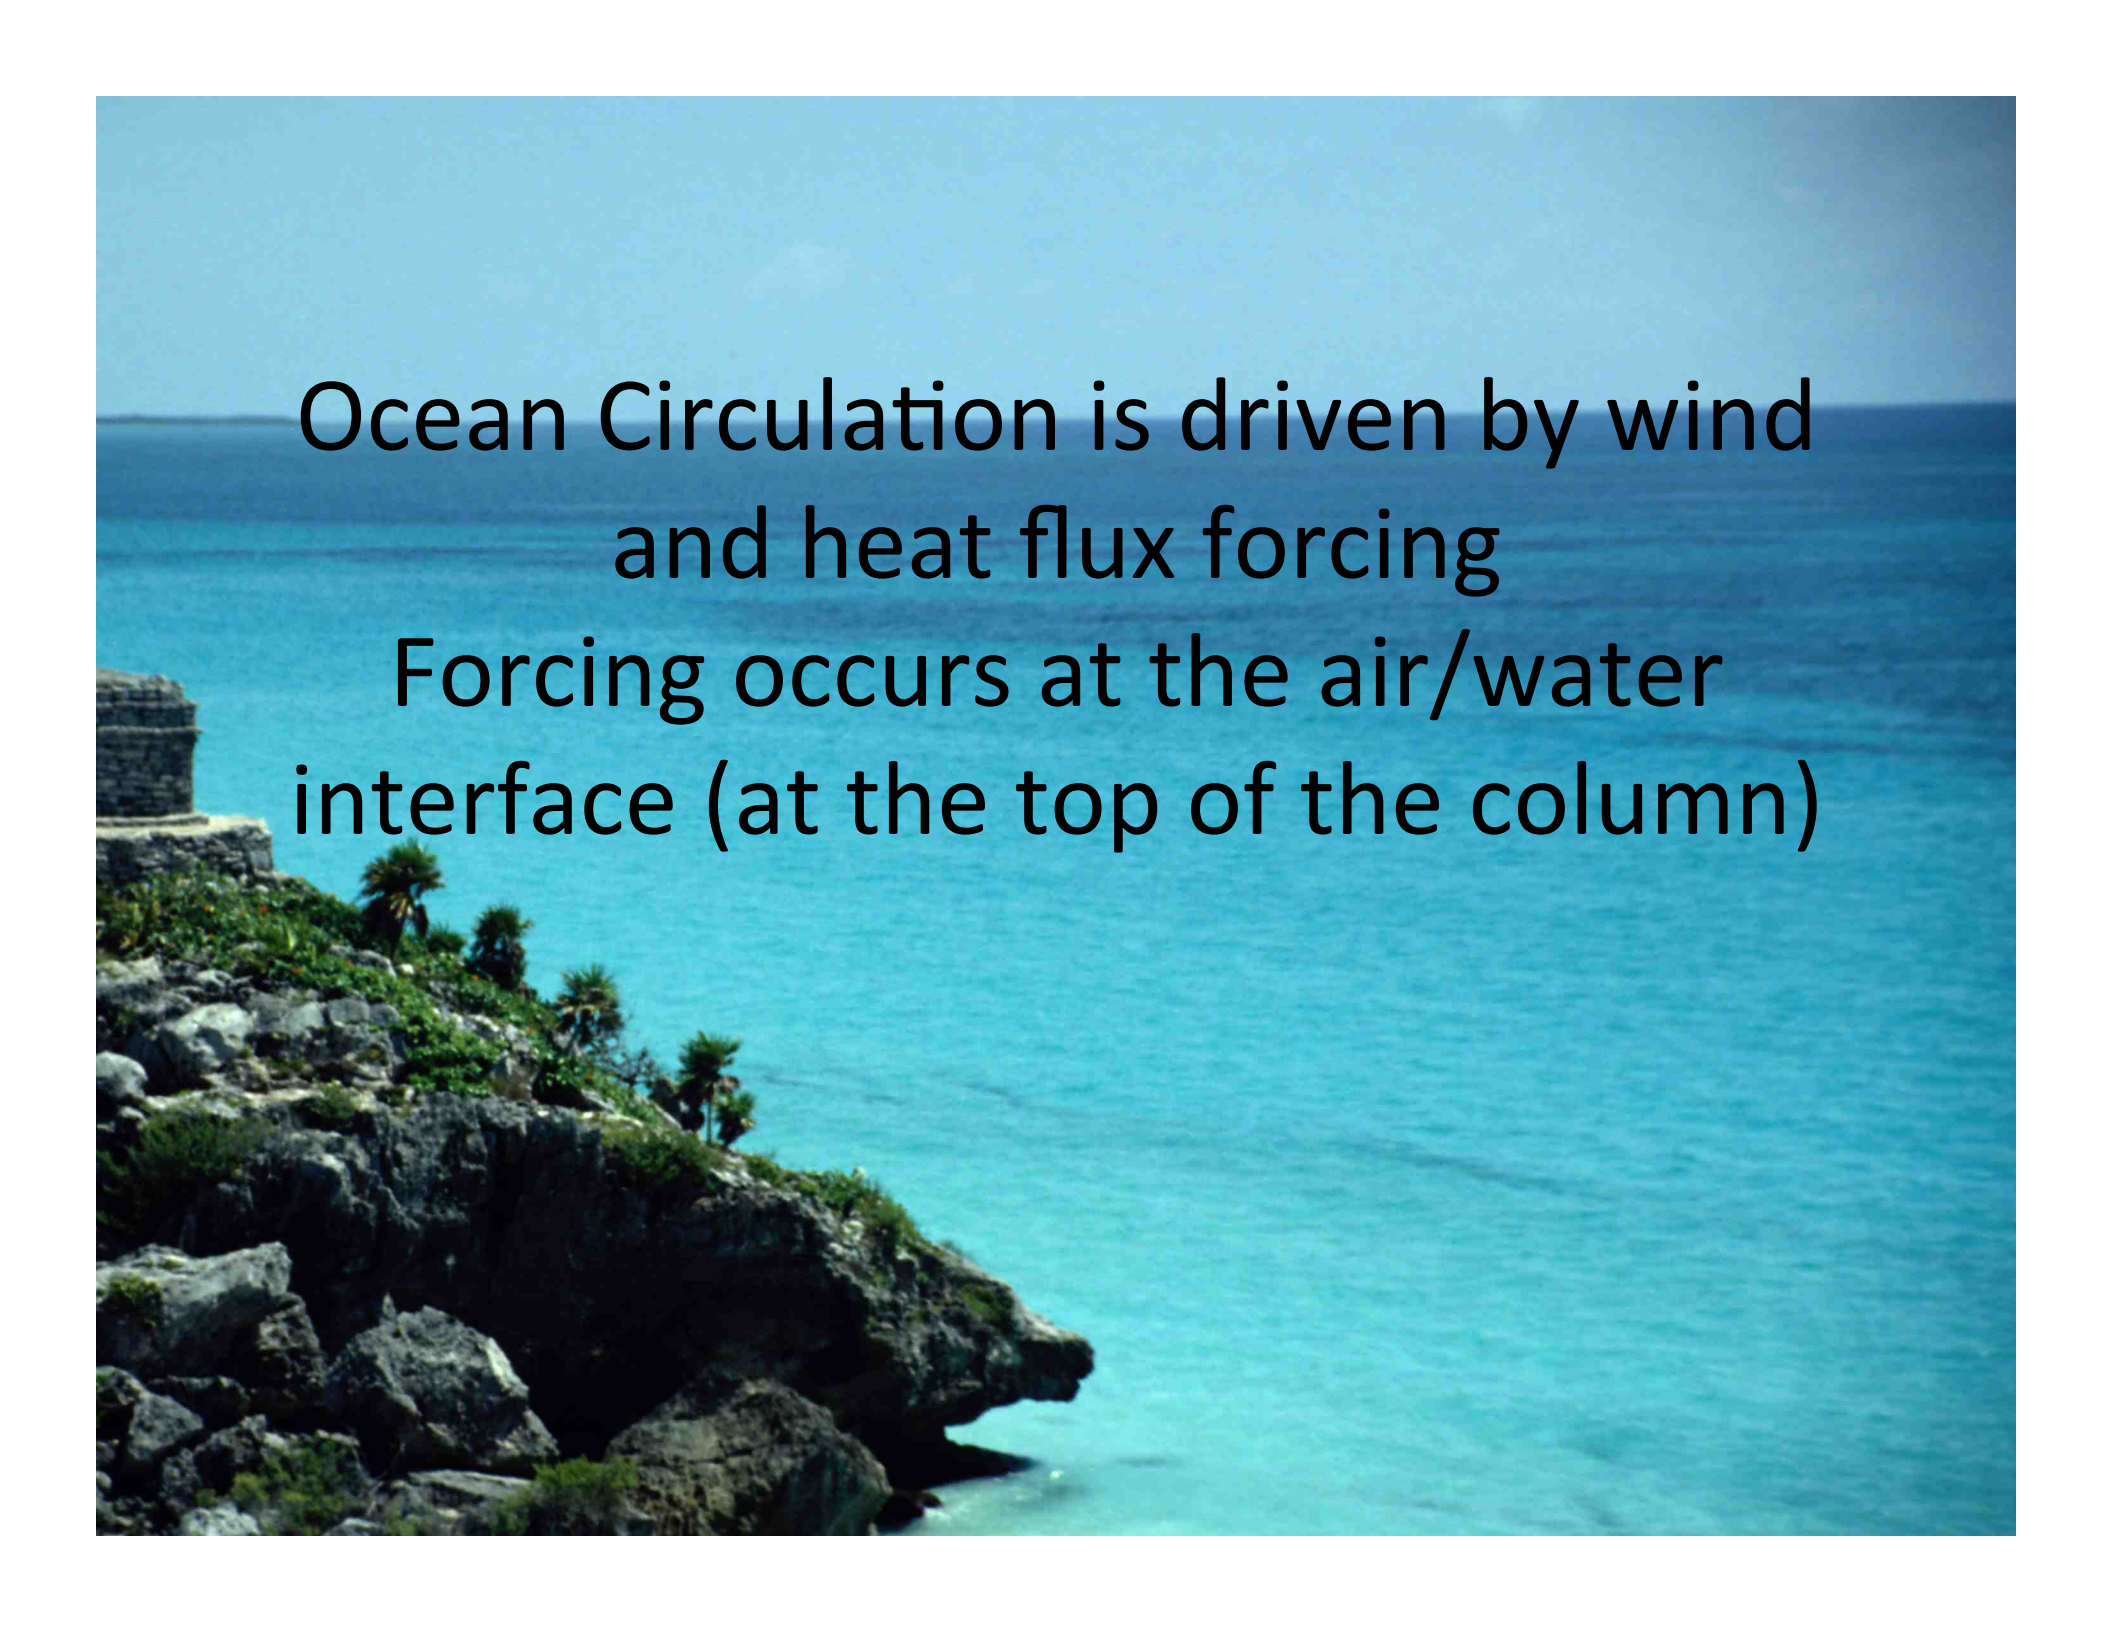

# Global Heat Transport

M&P fig 8.13

(From Trenberth and Caron (2001).)

A scenic view of a rocky coastline with turquoise water and a clear blue sky. The foreground shows dark, jagged rocks with some green vegetation and palm trees. The water is a vibrant turquoise color, and the sky is a clear, pale blue. The text is overlaid in the center of the image.

Ocean Circulation is driven by wind  
and heat flux forcing  
Forcing occurs at the air/water  
interface (at the top of the column)

# Winds

- Winds blow over the ocean, exerting a frictional stress
- The water moves in response
- The response is strongly modulated by rotation

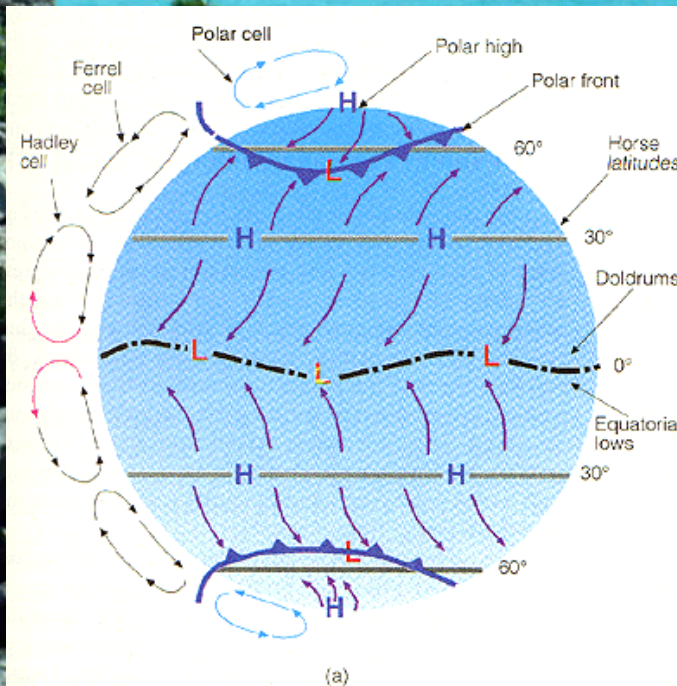

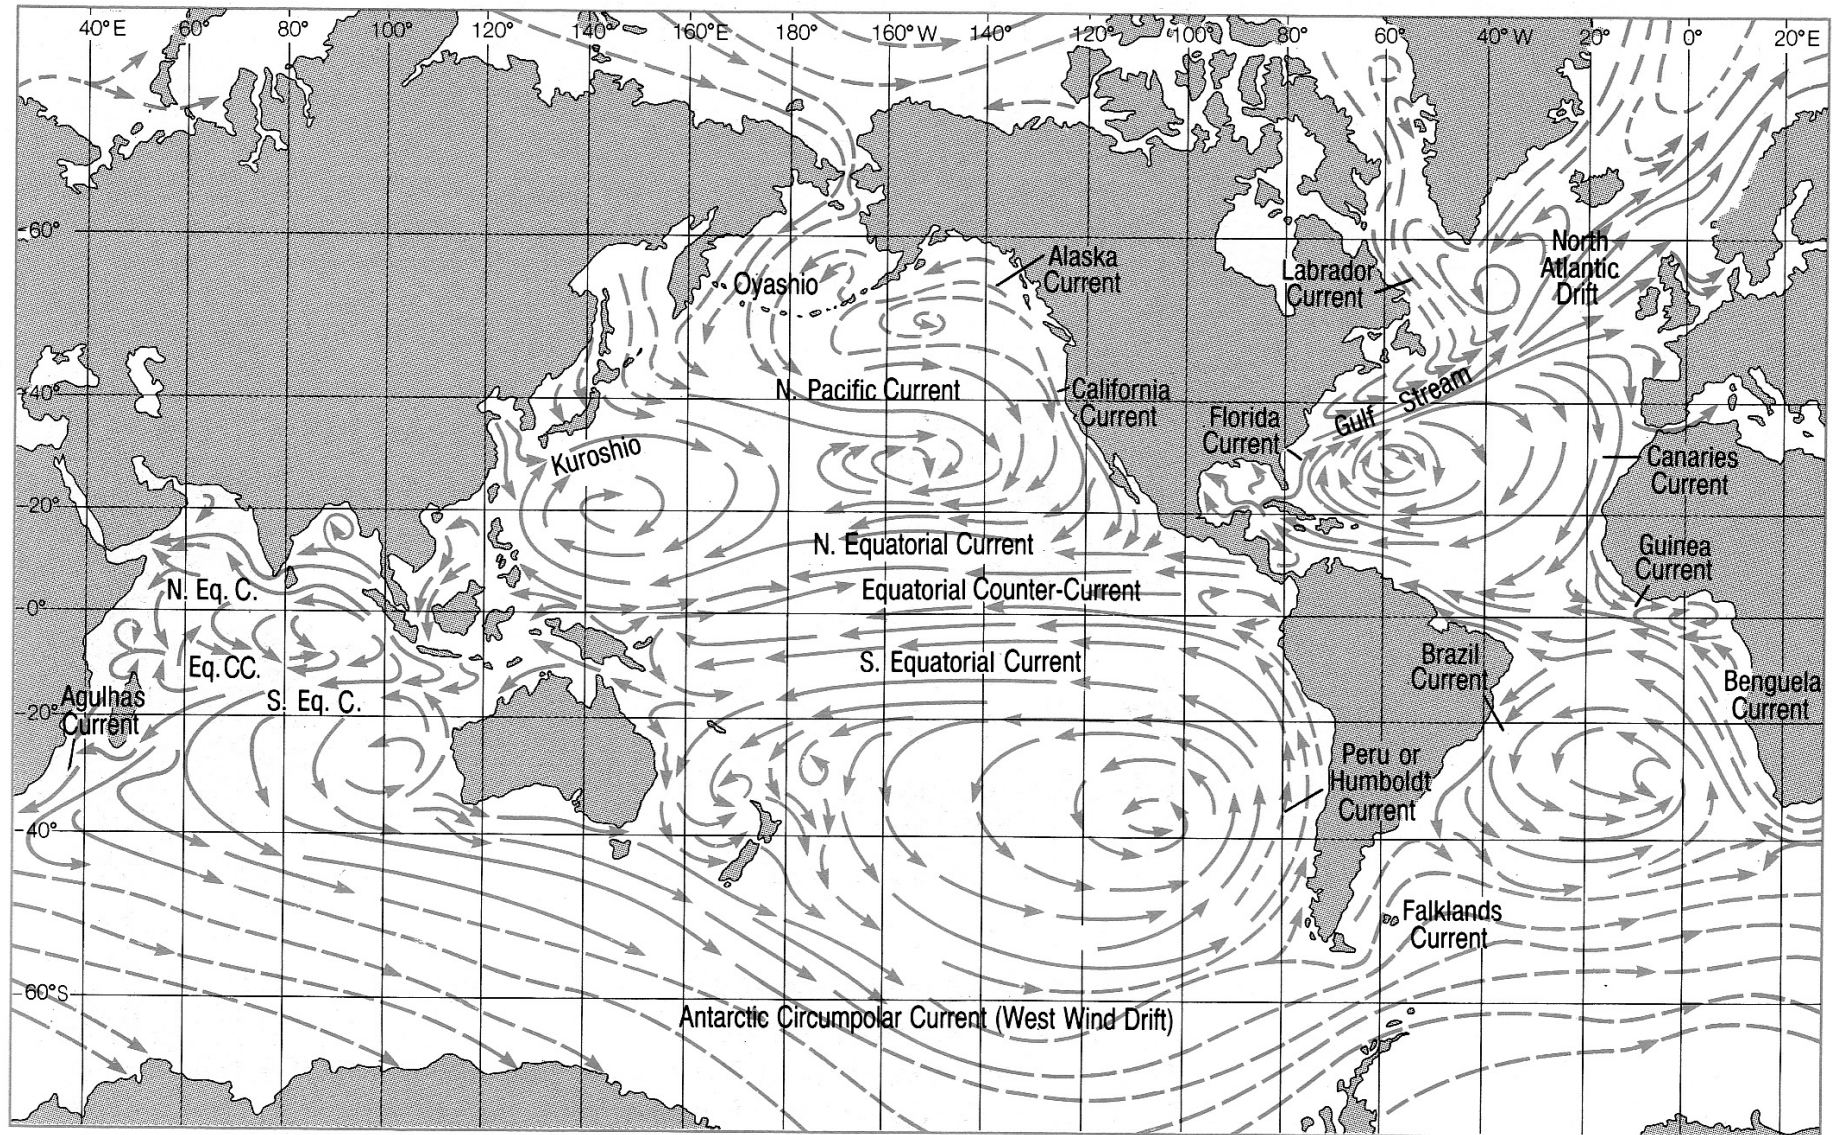

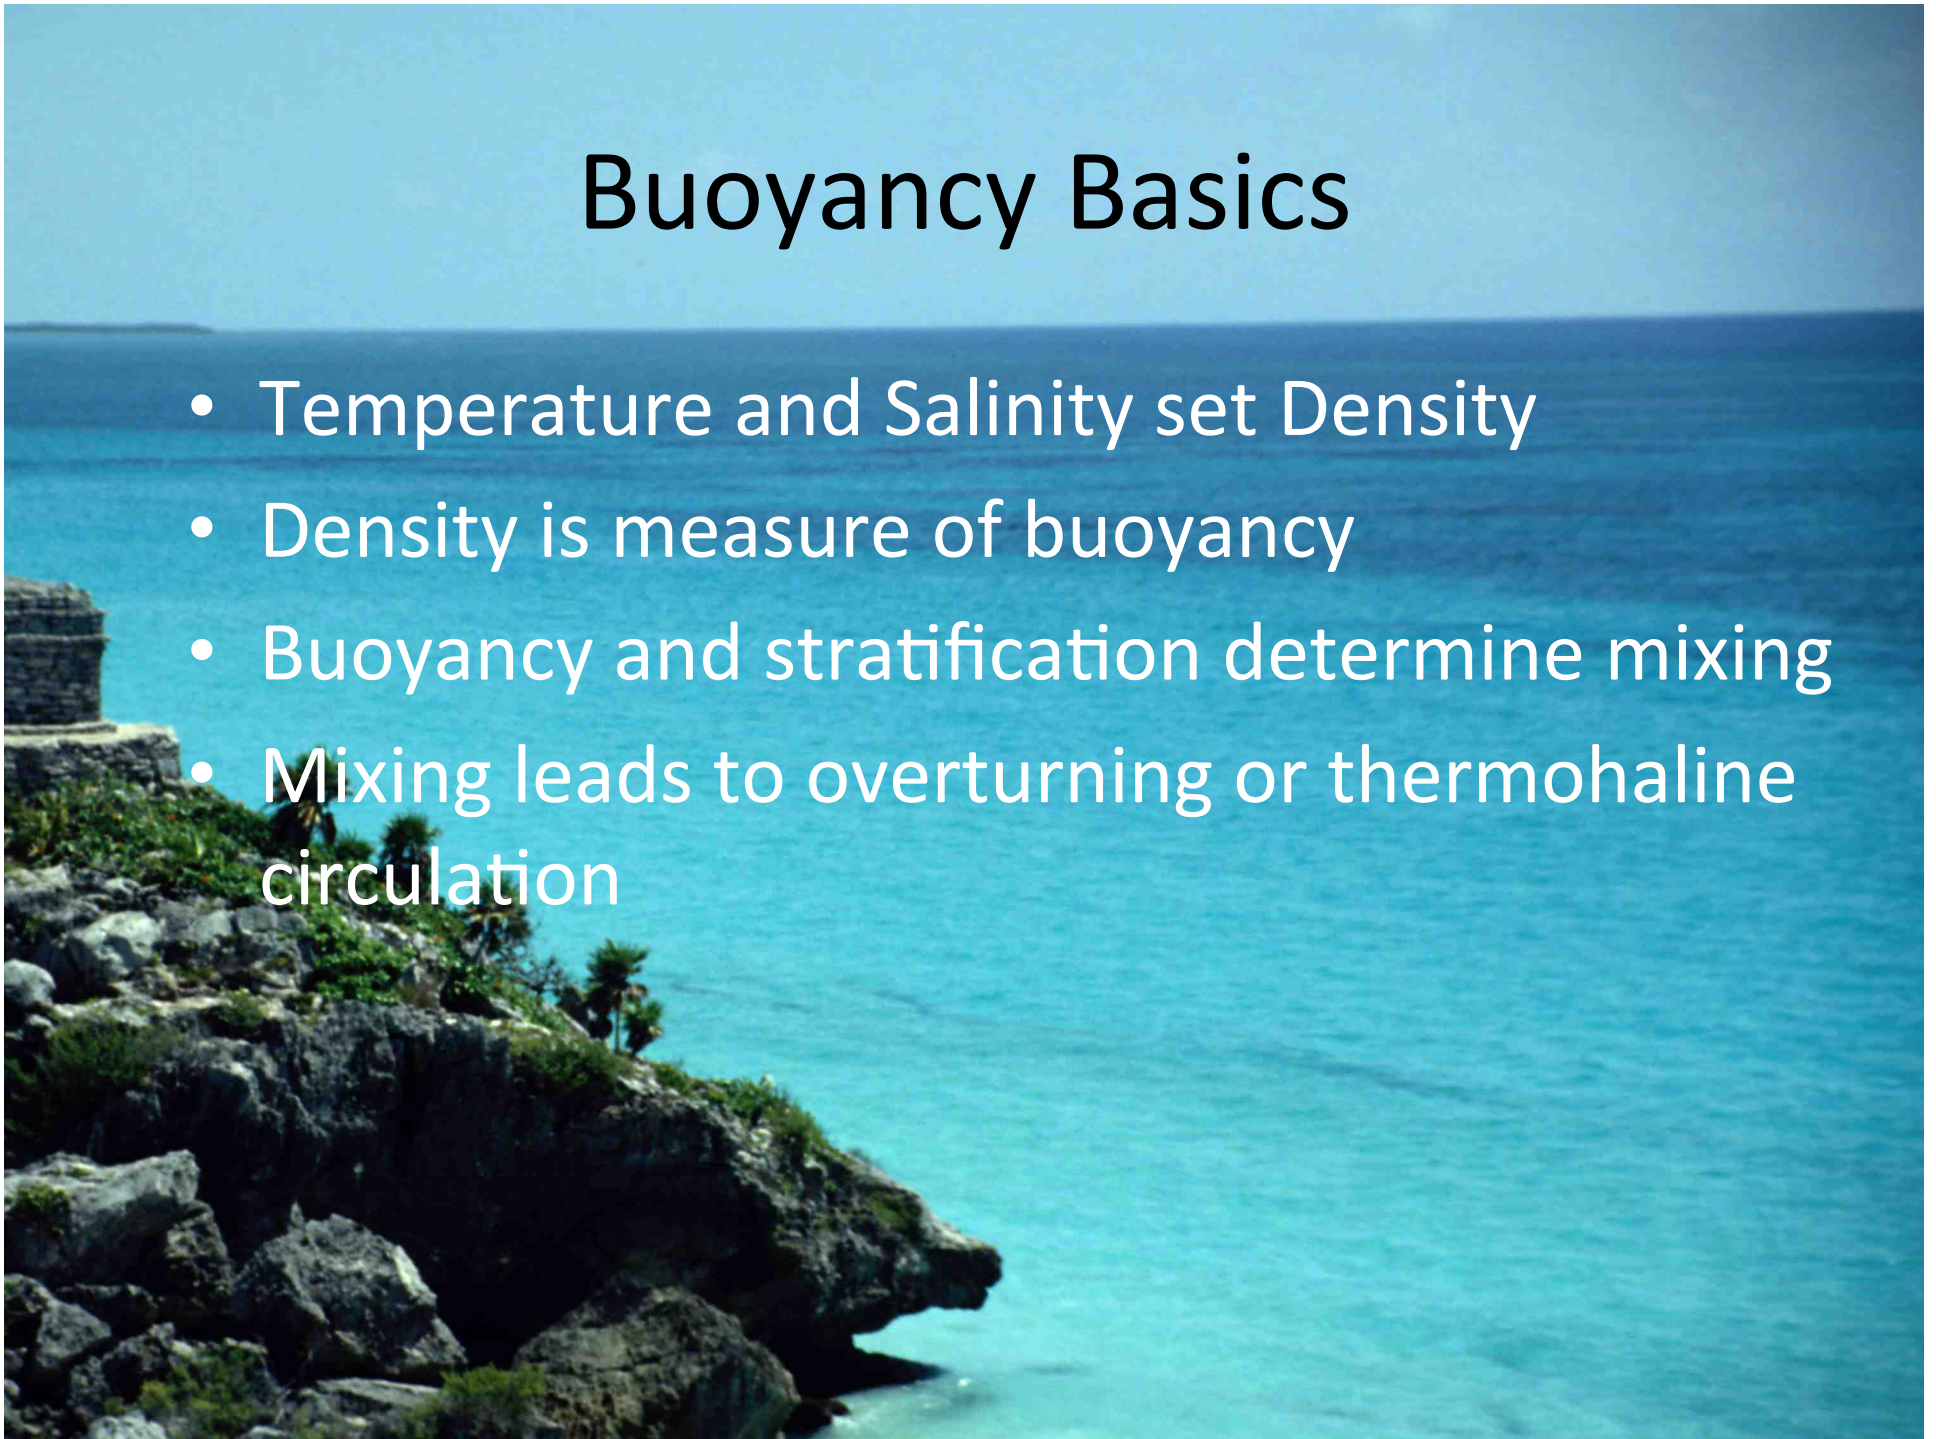

Figure 9.3. Ekman current generated by a 10 m/s wind at 35° N.

Open University, Ocean Circulation, Fig 3.1

# Buoyancy Basics

- Temperature and Salinity set Density
- Density is measure of buoyancy
- Buoyancy and stratification determine mixing
- Mixing leads to overturning or thermohaline circulation

# An oceanographic section

# WOCE: World Ocean Circulation Experiment (1990-2002)

First systematic, global hydrographic survey

A scenic view of a rocky coastline with turquoise water and a clear blue sky. The text "The ocean is vastly undersampled" is overlaid in the center.

The ocean is vastly  
undersampled

# Impression of smooth flow is erroneous

- The traditional view of a smooth, steady flow is largely due to insufficient observation of variability

# 1 year coupled climate simulation

Ocean:  $0.1^{\circ}$  to  $0.25^{\circ}$

Atmosphere:  $1^{\circ}$

# Oceans and anthropogenic climate change

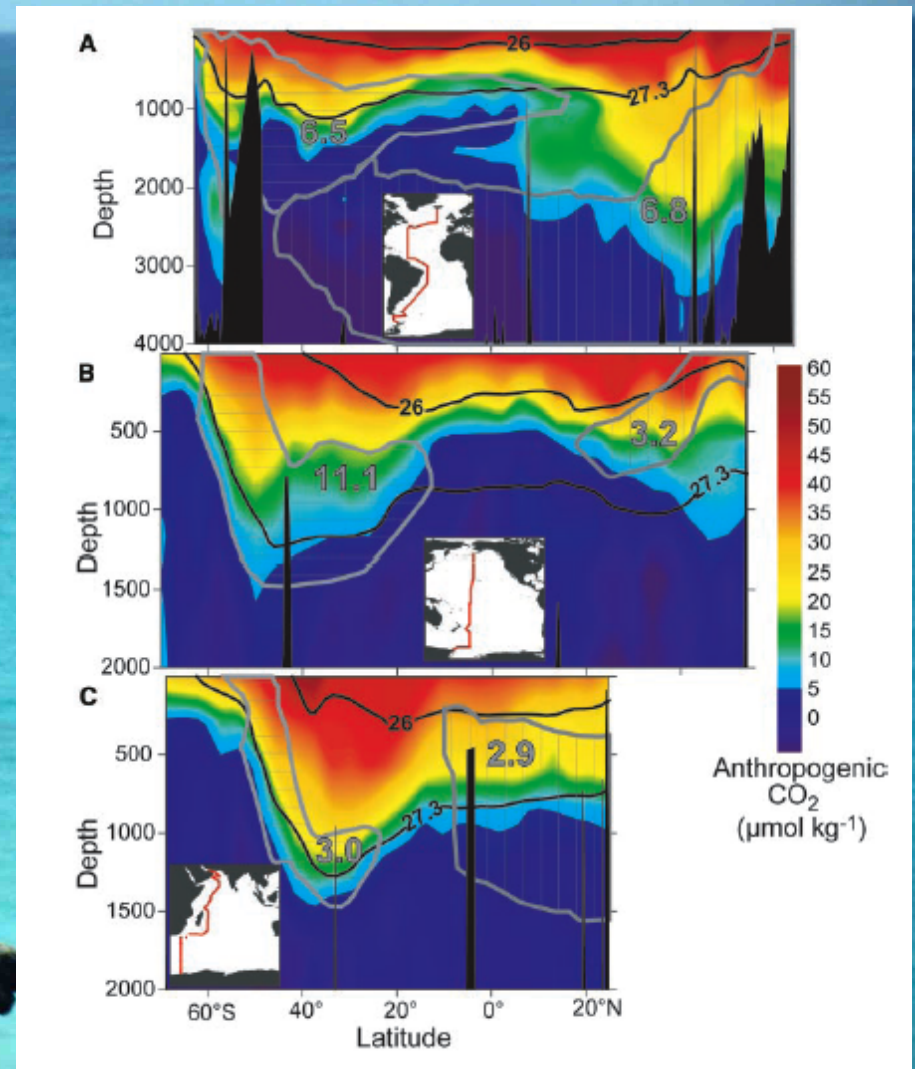

# Ocean's large heat capacity allows substantial modulation of climate warming

**Figure 3.** Estimates of Earth's heat balance components ( $10^{22}$  J) for the 1955–1998 period.

Levitus et al. 2005

# Oceans absorb anthropogenic CO<sub>2</sub>

48% of anthropogenic carbon since 1800 has been absorbed

~25% of current annual output is absorbed

Sabine et al. 2004

# But the uptake also drives acidification – ecological impacts?

Doney 2006

Before the Industrial Revolution (*left*), most surface waters were substantially “oversaturated” with respect to aragonite (*light blue*), allowing marine organisms to form this mineral readily. But now (*center*), polar surface waters are only marginally oversaturated (*dark blue*). At the end of this century (*right*), such chilly waters, particularly those surrounding Antarctica, are expected to become undersaturated (*purple*), making it difficult for organisms to make aragonite and causing aragonite already formed to dissolve.

# Summary

- Ocean is integral to the climate system. It carries substantial heat from equator to pole.
- Circulation can be explained by Navier Stokes on a rotating sphere, forced by winds and buoyancy fluxes at the surface
- The ocean is vastly undersampled
- The flow is not smooth -- Eddies are everywhere
- The large heat capacity of the ocean affords it “memory” important on anthropogenic timescales
- The ocean’s role in the carbon cycle is critical to understanding and predicting anthropogenic climate change

# Current Research

- Knowledge of the ocean is rapidly expanding
- We will read and discuss papers this semester
- Student pairs will lead the discussion
- Everyone is expected to participate each time – your participation will be noted, and you may be called on at random

# Skills for ocean and climate research

- Data analysis
- Explore data to understand processes
- Use data to elucidate dynamical principles
- Literature review – discussion and presentation
- Technical writing

# Syllabus Review

- Please also read carefully before next class.
- Scheduling conflicts should be identified and discussed immediately
